

Farm data collection model Case grain dryer

The information collected from the drying batches of the crop is the time, plant species and variety, weight of the batch, initial and final humidity, temperature, duration of drying, oil and electricity consumption, cooling time and outside air temperature. Things to be analyzed are, for example, the effects of the initial humidity of the batch and outside temperature on the energy consumption.

For conclusions, information is needed, e.g. to determine the most economical harvest time.
